Step 3: The Symbolic Core - Foundational Math

This section defines the pure mathematical logic of our problem using Python's `sympy` library. Each function in this section is a “blueprint” for a physical calculation.

These functions take symbolic `sympy` objects as input and return new symbolic expressions as output. They have no knowledge of C code; they are concerned only with mathematics and will be called later to generate the “recipes” for our C code engines.

3.a: Metric Tensor Derivatives

The first step in calculating the Christoffel symbols is to compute the partial derivatives of the metric tensor, $g_{\mu\nu}$. This function, `derivative_g4DD`, takes the symbolic 4x4 metric tensor `g4DD` and a list of the four coordinate symbols `xx` as input.

The function iterates through all components to symbolically calculate the partial derivative of each metric component with respect to each coordinate. The resulting quantity, which we can denote using comma notation as $g_{\mu\nu,\alpha}$, is defined as:

$$g_{\mu\nu,\alpha} \equiv \frac{\partial g_{\mu\nu}}{\partial x^\alpha}$$

The nested `for` loops in the code directly correspond to the spacetime indices μ , ν , α in the physics equation. `sympy`’s built-in `sp.diff()` function is used to perform the symbolic differentiation, and the final result is returned as a rank-3 symbolic tensor.

1.0.1 nrpy Functions Used in this Cell:

- `nrpy.indexedexp.zerorank3(dimension):`
 - **Source File:** `nrpy/indexedexp.py`
 - **Description:** This function creates a symbolic rank-3 tensor (a Python list of lists of lists) of a specified dimension, with all elements initialized to the `sympy` integer 0. It is used here to create a container for the derivative results.

```
[2]: def derivative_g4DD(g4DD, xx):
      """Computes the symbolic first derivatives of the metric tensor."""
      g4DD_dD = ixp.zerorank3(dimension=4)
      for nu in range(4):
          for mu in range(4):
              for alpha in range(4):
                  g4DD_dD[nu][mu][alpha] = sp.diff(g4DD[nu][mu], xx[alpha])
      return g4DD_dD
```

3.b: Christoffel Symbol Calculation

This function implements the core formula for the Christoffel symbols of the second kind, $\Gamma_{\mu\nu}^\delta$. It takes the symbolic metric tensor `g4DD` ($g_{\mu\nu}$) and its derivatives `g4DD_dD` ($g_{\mu\nu,\alpha}$) as input. The calculation requires the inverse metric, $g^{\mu\nu}$, which is computed using another `nrpy` helper function.

The function then applies the well-known formula for the Christoffel symbols. Using the comma notation for partial derivatives, the formula is:

$$\Gamma_{\mu\nu}^\delta = \frac{1}{2} g^{\delta\alpha} (g_{\nu\alpha,\mu} + g_{\mu\alpha,\nu} - g_{\mu\nu,\alpha})$$

The Python `for` loops iterate over the spacetime indices δ , μ , ν , α to construct each component of the Christoffel symbol tensor. After the summation is complete, the `sp.trigsimp()` function is used to simplify the resulting expression. This trigonometric simplification is highly effective and much faster than a general `sp.simplify()` for the Kerr-Schild metric, which contains trigonometric functions of the coordinates.

1.0.2 nrpy Functions Used in this Cell:

- `nrpy.indexedexp.zerorank3(dimension)`: Previously introduced. Used to initialize the Christoffel symbol tensor.
- `nrpy.indexedexp.symm_matrix_inverter4x4(g4DD)`:
 - **Source File**: `nrpy/indexedexp.py`
 - **Description**: This function takes a symbolic 4x4 symmetric matrix and analytically computes its inverse. It is highly optimized for this specific task, returning both the inverse matrix ($g^{\mu\nu}$) and its determinant.

```
[3]: def four_connections(g4DD, g4DD_dD):
    """
    Computes and simplifies Christoffel symbols from the metric and its derivatives.

    This version uses sp.trigsimp() which is highly effective and much faster
    than sp.simplify() for the Kerr-Schild metric.
    """
    Gamma4UDD = ixp.zerorank3(dimension=4)
    g4UU, _ = ixp.symm_matrix_inverter4x4(g4DD)

    for mu in range(4):
        for nu in range(4):
            for delta in range(4):
                # Calculate the Christoffel symbol component using the standard formula
                for alpha in range(4):
                    Gamma4UDD[delta][mu][nu] += sp.Rational(1, 2) * g4UU[delta][alpha] * \
                        (g4DD_dD[nu][alpha][mu] + g4DD_dD[mu][alpha][nu] - g4DD_dD[mu][nu][alpha])

                # Use sp.trigsimp() to simplify the resulting expression.
                # This is the key to speeding up the symbolic calculation.
                Gamma4UDD[delta][mu][nu] = sp.trigsimp(Gamma4UDD[delta][mu][nu])

    return Gamma4UDD
```

3.c: Geodesic Momentum RHS

This function defines the symbolic right-hand side (RHS) for the evolution of the **reverse-time momentum**, p^α . As established in the introduction, this is the second of our three first-order ODEs:

$$\frac{dp^\alpha}{d\kappa} = -\Gamma_{\mu\nu}^\alpha p^\mu p^\nu$$

The function `geodesic_mom_rhs` takes the symbolic Christoffel symbols $\Gamma_{\mu\nu}^\alpha$ as its input. It then defines the symbolic momentum vector `pU` using `sympy`’s `sp.symbols()` function. A key `nrpy` technique is used here: the symbols are created with names that are already valid C array syntax (e.g., `"y[4]"`). This “direct naming” simplifies the final C code generation by eliminating the need for string substitutions.

The core of this function constructs the symbolic expression for the RHS by performing the Einstein summation $-\Gamma_{\mu\nu}^\alpha p^\mu p^\nu$. A direct implementation would involve a double loop over both μ and ν from 0 to 3, resulting in $4 \times 4 = 16$ terms for each component of α , which is computationally inefficient.

However, we can significantly optimize this calculation by exploiting symmetry. The term $p^\mu p^\nu$ is symmetric with respect to the interchange of the indices μ and ν .

The Christoffel symbols $\Gamma_{\mu\nu}^\alpha$ are also symmetric in their lower two indices. Therefore, the full sum can be split into diagonal ($\mu = \nu$) and off-diagonal ($\mu \neq \nu$) terms:

$$\sum_{\mu,\nu} \Gamma_{\mu\nu}^\alpha p^\mu p^\nu = \sum_{\mu=0}^3 \Gamma_{\mu\mu}^\alpha (p^\mu)^2 + \sum_{\mu \neq \nu} \Gamma_{\mu\nu}^\alpha p^\mu p^\nu$$

The second sum over $\mu \neq \nu$ contains pairs of identical terms (e.g., the $\mu = 1, \nu = 2$ term is the same as the $\mu = 2, \nu = 1$ term). We can combine all such pairs by summing over only one of the cases (e.g., $\mu < \nu$) and multiplying by two:

$$\sum_{\mu,\nu} \Gamma_{\mu\nu}^\alpha p^\mu p^\nu = \sum_{\mu=0}^3 \Gamma_{\mu\mu}^\alpha (p^\mu)^2 + 2 \sum_{\mu < \nu} \Gamma_{\mu\nu}^\alpha p^\mu p^\nu$$

The Python code implements this optimized version, ensuring that each component of the RHS is computed with the minimum number of floating point operations, leading to more efficient C code.

1.0.3 nrpy Functions Used in this Cell:

- `nrpy.indexedexp.zerorank1(dimension):`
 - **Source File:** `nrpy/indexedexp.py`
 - **Description:** Creates a symbolic rank-1 tensor (a Python list) of a specified dimension, with all elements initialized to the `sympy` integer 0. It is used here to create a container for the four components of the momentum RHS.

```
[4]: def geodesic_vel_rhs_massive():
    """
    Symbolic RHS for massive particle velocity ODE: du^a/dτ = -Γ^a_μν u^μ u^ν.
    u is the 4-velocity, y[4]...y[7].
    """
    Gamma4UDD = ixp.declarerank3("conn->Gamma4UDD",dimension= 4,sym="sym12")
    ut,ux,uy,uz = sp.symbols("y[4] y[5] y[6] y[7]", Real=True)
    uU = [ut,ux,uy,uz]
    geodesic_rhs = ixp.zerorank1(dimension=4)
    for alpha in range(4):
        for mu in range(4):
            geodesic_rhs[alpha] += Gamma4UDD[alpha][mu][mu] * uU[mu] * uU[mu]
        for nu in range(mu + 1, 4):
            geodesic_rhs[alpha] += 2 * Gamma4UDD[alpha][mu][nu] * uU[mu] * uU[nu]
        geodesic_rhs[alpha] = -geodesic_rhs[alpha]
    return geodesic_rhs
```

3.d: Geodesic Position RHS

This function defines the symbolic right-hand side (RHS) for the evolution of the position coordinates, x^α . As derived in the introduction, this is the first of our three first-order ODEs:

$$\frac{dx^\alpha}{d\kappa} = p^\alpha$$

The Python function `geodesic_pos_rhs` is straightforward. It defines the components of the reverse-time momentum vector, p_U , using sympy's `sp.symbols()` function with the “direct naming” convention (`y[4]`, `y[5]`, etc.). It then simply returns a list containing these momentum components. This list of four symbolic expressions will serve as the first four components of the complete 9-component RHS vector that our C code will solve.

```
[5]: def geodesic_pos_rhs_massive():
    """
    Symbolic RHS for position ODE:  $dx^a/d\tau = u^a$ .
     $u$  is the 4-velocity,  $y[4] \dots y[7]$ .
    """
    ut,ux,uy,uz = sp.symbols("y[4] y[5] y[6] y[7]", Real=True)
    uU = [ut,ux,uy,uz]
    return uU
```

3.f: Symbolic Calculation of u^0

```
[6]: def ut_massive():
    """
    Symbolically derives  $u^t$  for a MASSIVE particle from the 4-velocity.
    The derivation comes from solving the timelike normalization condition  $g_{\mu\nu} u^\mu u^\nu = -1$ .
    """
    # The symbolic recipe will use the standard variable names u0, u1, etc.
    # The C-generating function will map y[4], y[5], etc. to these.
    u0,u1,u2,u3 = sp.symbols("u0 u1 u2 u3", Real=True)

)

return Q_final

print("Final symbolic recipes for conserved quantities defined (Carter Constant re-derived).")

```

Final symbolic recipes for conserved quantities defined (Carter Constant re-derived).

Step 4: Spacetime Definition in Kerr-Schild Coordinates

This section defines the specific spacetime geometry in which the geodesics will be integrated. Instead of defining separate metrics for Schwarzschild (non-rotating) and Kerr (rotating) black holes, we use a single, powerful coordinate system: **Cartesian Kerr-Schild coordinates**. This system has a major advantage over more common coordinate systems like Boyer-Lindquist: it is regular everywhere, including at the event horizon. This means the metric components and their derivatives do not diverge, allowing the numerical integrator to trace a photon's path seamlessly across the horizon without encountering coordinate singularities.

The Kerr-Schild metric $g_{\mu\nu}$ is constructed by adding a correction term to the flat Minkowski metric $\eta_{\mu\nu}$:

$$g_{\mu\nu} = \eta_{\mu\nu} + 2Hl_\mu l_\nu$$

where $\eta_{\mu\nu}$ is the Minkowski metric $\text{diag}(-1, 1, 1, 1)$, l_μ is a special null vector, and H is a scalar function that depends on the black hole's mass M and spin a .

The function `define_kerr_metric_Cartesian_Kerr_Schild()` implements this formula symbolically. It defines the coordinates (t, x, y, z) , the mass M , and the spin a as `sympy` symbols. It then constructs the components of the null vector l_μ and the scalar function H . Finally, it assembles the full metric tensor $g_{\mu\nu}$.

A key feature of this formulation is that if the spin parameter `a` is set to zero, the metric automatically and exactly reduces to the Schwarzschild metric in Cartesian coordinates. This allows a single set of symbolic expressions and a single set of C functions to handle both spacetimes, with the specific behavior controlled by the runtime value of the `a_spin` parameter.

5.0.1 `nrpy` Functions Used in this Cell:

- `nrpy.indexedexp.zerorank1(dimension)`: Previously introduced. Used to initialize the null vector l_μ .

- `nrpy.indexedexp.zerorank2(dimension)`: Previously introduced. Used to initialize the metric tensor $g_{\mu\nu}$.

```
[11]: def define_kerr_metric_Cartesian_Kerr_Schild():
    """
    Defines the Kerr metric tensor in Cartesian Kerr-Schild coordinates.

    This function is the new, unified source for both Kerr ( $a \neq 0$ ) and
    Schwarzschild ( $a = 0$ ) spacetimes. The coordinates are  $(t, x, y, z)$ .

    Returns:
        A tuple  $(g_{4DD}, \text{xx})$ , where  $g_{4DD}$  is the symbolic  $4 \times 4$  metric tensor

Step 5: Symbolic Workflow Execution

This cell acts as the central hub for the symbolic portion of our project. In the preceding cells, we *defined* a series of Python functions that perform individual mathematical tasks. Here, we *execute* those functions in the correct sequence to generate all the final symbolic expressions that will serve as “recipes” for our C code generators.

This “symbolic-first” approach is a core **nrpy** principle and offers significant advantages: 1. **Efficiency**: The complex symbolic calculations, such as inverting the metric tensor and deriving the Christoffel symbols, are performed **only once** when this notebook is run. The results are stored in global Python variables, preventing redundant and time-consuming recalculations. This is especially important for the Kerr metric, whose Christoffel symbols can take several minutes to compute. 2. **Modularity**: This workflow creates a clean separation between the *specific solution* for a metric (e.g., the explicit formulas for the Kerr-Schild Christoffels) and the *generic form* of the equations of motion (which are valid for any metric).

This cell produces two key sets of symbolic expressions that are stored in global variables for later use: * **Gamma4UDD_kerr**: The explicit symbolic formulas for the Christoffel symbols of the unified Kerr-Schild metric. * **all_rhs_expressions**: A Python list containing the 9 symbolic expressions for the right-hand-sides of our generic ODE system. To achieve this generality, we create a symbolic **placeholder** for the Christoffel symbols using `ixp.declarerank3("conn->Gamma4UDD", ...)`. This placeholder is passed to `geodesic_mom_rhs()` to construct the geodesic equation in its abstract form. This elegant technique embeds the final C variable name (`conn->Gamma4UDD...`) directly into the symbolic expression, which dramatically simplifies the C code generation step for the `calculate_ode_rhs()` engine.

6.0.1 nrpy Functions Used in this Cell:

- `nrpy.indexedexp.declarerank3(name, dimension)`: Previously introduced. Used here to create a symbolic placeholder for the Christoffel symbols that will be passed to the generic RHS engine.

```

Step 6: C Code Generation - Physics “Engines” and “Workers”

This section marks our transition from pure symbolic mathematics to C code generation. The Python functions defined here are “meta-functions”: their job is not to perform calculations themselves, but to **generate the C code** that will perform the calculations in the final compiled program.

We distinguish between two types of generated functions: * **Workers**: These are specialized functions that implement the physics for a *specific metric*. For example, `con_kerr_schild()` is a worker that only knows how to compute Christoffel symbols for the Kerr-Schild metric. * **Engines**: These are generic functions that implement physics equations valid for *any metric*. For example, `calculate_ode_rhs()` is an engine that can compute the geodesic equations for any metric, as long as the Christoffel symbols are provided to it.

This design pattern allows for maximum code reuse and extensibility.

7 Schwarzschild Metric

```
[14]: def g4DD_schwarzschild_cartesian():
    """
    Generates and registers the C function to compute the Schwarzschild
    metric components in standard Cartesian coordinates.
    """
    print(" -> Generating C worker function: g4DD_schwarzschild_cartesian()...")

    # Use the globally defined g4DD_schw_cart from the symbolic execution step
    list_of_g4DD_syms = []
    for i in range(4):
        for j in range(i, 4):
            list_of_g4DD_syms.append(g4DD_schw_cart[i][j])

    list_of_g4DD_C_vars = []
    for i in range(4):
        for j in range(i, 4):
            list_of_g4DD_C_vars.append(f"metric->g{i}-{j}")

    includes = ["BHaH_defines.h"]
    desc = r"""@brief Computes the 10 unique components of the Schwarzschild metric in Cartesian coords."""
    name = "g4DD_schwarzschild_cartesian"
    params = "const commondata_struct *restrict commondata, const params_struct *restrict params, const double y[4], metric_struct_
    ↪*restrict metric"

    body = ccg.c_codegen(list_of_g4DD_syms, list_of_g4DD_C_vars, enable_cse=True)

    cfc.register_CFunction(
        includes=includes, desc=desc, name=name, params=params, body=body,
        include_CodeParameters_h=True
    )
    print(" ... g4DD_schwarzschild_cartesian() registration complete.")
```

6.a: g4DD_kerr_schild() Worker

This Python function generates the C **worker** function `g4DD_kerr_schild()`, whose only job is to compute the 10 unique components of the Kerr-Schild metric tensor, $g_{\mu\nu}$, at a given point in spacetime.

The generation process is as follows: 1. **Access Symbolic Recipe:** It accesses the global `g4DD_kerr` variable, which holds the symbolic `sympy` expression for the Kerr-Schild metric tensor, generated in Step 5. 2. **Define C Assignment:** It creates two Python lists: one containing the 10 unique symbolic metric expressions (`list_of_g4DD_syms`) and another containing the corresponding C variable names for the members of the `metric_struct` (e.g., `metric->g00`, `metric->g01`, etc.) in `list_of_g4DD_C_vars`. 3. **Generate C Code:** It passes these two lists to `nrpy.c_codegen.c_codegen`. This powerful `nrpy` function converts the symbolic math into highly optimized C code, including performing Common Subexpression Elimination (CSE). 4. **Register C Function:** Finally, it bundles the generated C code with its metadata (description, parameters, etc.) and registers the complete function with `nrpy.c_function.register_CFunction`. Crucially, it sets `include_CodeParameters_h=True` to automatically handle access to both the `M_scale` and `a_spin` parameters via the “Triple-Lock” system.

7.0.1 nrpy Functions Used in this Cell:

- `nrpy.c_codegen.c_codegen(sympy_expressions, C_variable_names, **kwargs)`:
 - **Source File:** `nrpy/c_codegen.py`
 - **Description:** The core symbolic-to-C translation engine. It takes a list of `sympy` expressions and a corresponding list of C variable names and generates optimized C code to perform the assignments.
 - **Key Inputs:**
 - * `sympy_expressions`: A Python list of symbolic expressions to be converted to C code.
 - * `C_variable_names`: A Python list of strings for the C variables that will store the results.
 - **Key Keyword Arguments (kwargs):**
 - * `enable_cse=True`: Enables Common Subexpression Elimination, which finds repeated mathematical operations, assigns them to temporary variables, and reuses those variables to reduce redundant calculations. This is essential for performance.
- `nrpy.c_function.register_CFunction(name, params, body, **kwargs)`:
 - **Source File:** `nrpy/c_function.py`
 - **Description:** This is the workhorse for defining a C function. It takes all necessary metadata and stores it in a global dictionary, `cfc.CFunction_dict`. The final build system uses this dictionary to write all the `.c` source files.
 - **Key Inputs:**
 - * `name`: The name of the C function.
 - * `params`: A string defining the function's parameters (e.g., `"const double y[4], ..."`).
 - * `body`: A string containing the C code for the function's body.
 - **Key Keyword Arguments (kwargs):**
 - * `include_CodeParameters_h=True`: Enables the "Triple-Lock" system for this function, automatically including `set_CodeParameters.h` at the top of the function body.

```
[15]: def g4DD_kerr_schild():
    """
    Generates and registers the C function to compute the Kerr-Schild
    metric components in Cartesian coordinates. This is the new unified worker.
    """
    print(" -> Generating C worker function: g4DD_kerr_schild()...")

    # We use the globally defined g4DD_kerr from the symbolic execution step
    list_of_g4DD_syms = []
    for i in range(4):
        for j in range(i, 4):
            list_of_g4DD_syms.append(g4DD_kerr[i][j])

    list_of_g4DD_C_vars = []
    for i in range(4):
        for j in range(i, 4):
            list_of_g4DD_C_vars.append(f"metric->g{i}{j}")

    includes = ["BHaH_defines.h"]
    desc = r"""@brief Computes the 10 unique components of the Kerr metric in Cartesian Kerr-Schild coords."""
    name = "g4DD_kerr_schild"
```

```

# The state vector y now contains (t, x, y, z)
params = "const commondata_struct *restrict commondata, const params_struct *restrict params, const double y[4], metric_struct_
↪*restrict metric"

body = ccg.c_codegen(list_of_g4DD_syms, list_of_g4DD_C_vars, enable_cse=True)

cfc.register_CFunction(
    includes=includes, desc=desc, name=name, params=params, body=body,
    include_CodeParameters_h=True
)
print("    ... g4DD_kerr_schild() registration complete.")

```

6.b: con_kerr_schild() Worker

This function is structured identically to the `g4DD_kerr_schild` worker. It generates the C **worker** function `con_kerr_schild()`, whose only job is to compute the 40 unique Christoffel symbols for the unified Kerr-Schild metric.

The process is as follows: 1. **Access Symbolic Recipe:** It accesses the pre-computed symbolic Christoffel formulas from the global `Gamma4UDD_kerr` variable, which was generated in Step 5. 2. **Define C Assignment:** It creates a list of the 40 unique symbolic expressions and a corresponding list of the C variable names for the members of the `connection_struct` (e.g., `conn->Gamma4UDD012`). 3. **Generate C Code:** It uses `nrpy.c_codegen.c_codegen` to convert these highly complex symbolic expressions into optimized C code. The Common Subexpression Elimination (CSE) performed by `c_codegen` is absolutely essential here, as it reduces what would be thousands of floating-point operations into a much more manageable and efficient set of calculations. 4. **Register C Function:** Like the other workers, it registers the function using `nrpy.c_function.register_CFunction` and sets `include_CodeParameters_h=True` to handle its dependency on both `M_scale` and `a_spin`.

7.0.2 nrpy Functions Used in this Cell:

- `nrpy.indexedexp.declarerank3(name, dimension)`: Previously introduced. Used here to programmatically generate the C variable names for the Christoffel symbols that will be stored in the `connection_struct`.
- `nrpy.c_codegen.c_codegen(...)`: Previously introduced.
- `nrpy.c_function.register_CFunction(...)`: Previously introduced.

```

[16]: def con_kerr_schild():
    """

    include_CodeParameters_h=True
)
print("    ... con_schwarzschild_cartesian() registration complete.")

```

6.d: calculate_ode_rhs() Engine

This function generates the core “engine” of our ODE solver: the C function `calculate_ode_rhs()`. Its single responsibility is to calculate the right-hand sides for our entire system of 9 ODEs. It is completely generic and has no knowledge of any specific metric; it only knows how to compute the geodesic equations given a set of Christoffel symbols and the spatial metric components.

The generation process is straightforward: 1. **Access Generic Recipe:** It accesses the global `all_rhs_expressions` list. This list contains the generic symbolic form of the ODEs for position, momentum, and proper length that we derived in Step 5. 2. **Generate C Code:** It passes this list directly to `nrpy.c_codegen.c_codegen`. The symbols used to build `all_rhs_expressions` were already created with their final C syntax (e.g., `y[5]` for the momentum, `conn->Gamma4UDD...` for the Christoffel placeholder, and `metric->g...` for the metric placeholder). Therefore, no further symbolic manipulation is needed. `nrpy` simply translates the expressions into optimized C code. 3. **Register C Function:** The generated C code body is bundled with its metadata and registered. This function does not require the `include_CodeParameters_h` flag because it is physically generic and receives all necessary information through its arguments.

8.0.1 nrpy Functions Used in this Cell:

- `nrpy.c_codegen.c_codegen(...)`: Previously introduced.
- `nrpy.c_function.register_CFunction(...)`: Previously introduced.

```

```

Step 7: C Code Generation - Orchestrators and Dispatchers

With the low-level “engine” and “worker” functions defined in the previous step, we now generate the higher-level C functions that manage the simulation. These functions are responsible for dispatching to the correct worker based on runtime parameters and for orchestrating the overall program flow.

- **Dispatchers** are functions that contain a **switch** statement to select the correct “worker” function based on the chosen metric (e.g., **Schwarzschild** vs. **Kerr**).
- **Orchestrators** are functions that execute a sequence of calls to other engines, workers, and dispatchers to perform a complex task, like setting up initial conditions or running the main integration loop.

7.a: g4DD_metric() Dispatcher

This Python function generates the C function `g4DD_metric()`, which serves as a high-level **dispatcher**. Its role is to select and call the correct worker function to compute the components of the metric tensor, $g_{\mu\nu}$.

The generated C code uses a **switch** statement that reads the `metric->type` member of the `metric_params` struct. In this project, both the Schwarzschild and Kerr spacetimes are handled by the unified `g4DD_kerr_schild()` worker function. The dispatcher calls this single worker, and the specific metric returned by the worker depends on the runtime value of the `a_spin` parameter (if `a_spin` is 0, the Schwarzschild metric is computed).

This modular approach cleanly separates the control flow (deciding *which* metric to use) from the physics implementation (the worker functions that know *how* to compute a specific metric). This makes the project easy to extend with new spacetimes in the future by adding new cases to the **switch** statement and new worker functions.

9.0.1 nrpy Functions Used in this Cell:

- `nrpy.c_function.register_CFunction(...)`: Previously introduced. Used to register the manually written C code for the dispatcher function.

```

7.b: connections() Dispatcher

This Python function generates the C function `connections()`, which acts as a second **dispatcher**. Its sole responsibility is to select and call the correct metric-specific

worker function (like `con_kerr_schild()`) to compute the Christoffel symbols.

Like the `g4DD_metric()` dispatcher, the generated C code uses a `switch` statement based on the `metric->type`. It dispatches the call to the appropriate specialized worker, which in this case is the unified `con_kerr_schild()` function for both Kerr and Schwarzschild spacetimes. This design is highly extensible: adding a new metric simply requires writing a new worker function for its Christoffel symbols and adding a new `case` to this `switch` statement.

This function demonstrates how `nrpy` allows for the seamless integration of developer-written control flow with the automatically generated worker functions.

9.0.2 nrpy Functions Used in this Cell:
